

Microservices Architecture Diagram

Spring Boot Microservices Foundation — User Service, Product Service and Order Service

Each service runs independently and owns its own data. Communication between services is through APIs, not shared database access.

Architecture / Service Ownership

Service	Port	Primary Responsibility	Database Boundary
User Service	8081	User CRUD and User Data ownership	user_db
Product Service	8082	Product-related operations and Product Data ownership	Product database / configured store
Order Service	8083	Create, retrieve, update, cancel and delete orders	order_db

Key boundary rule: The Order Service must not directly access the User Service database. When user information is required, the Order Service communicates with the User Service through its REST API. Each service can run independently.
